OP Labs

Business Intelligence Lead
Take-Home Exercise

Thank you for taking the time to complete this exercise!

This project is designed to simulate the type of work the Business Intelligence Lead does every week: take an ambiguous question from leadership, decide what actually matters, reconcile messy public & internal data, and turn it into a recommendation someone can act on.

Time expectation: 3 to 4 hours. We don't expect every part to be polished.
Format: Slides/presentation that walks through your process alongside the results.
Presentation: 45-minute discussion with panel members from Data & Strategy, Business Development, and Finance.
Code & Data: Share your SQL, spreadsheets, and/or notebooks. If you used AI tools, tell us where and how you checked the output. A git repo would be impressive.

Case Study Prompt

You've joined OP Labs as Business Intelligence Lead. In your second week, leadership asks a deceptively simple question:

Who is making money on OP Mainnet, how much is our share, and how can we grow our take over the next 12 months?

Using the internal data we provide (below) plus any public sources (Dune/Allium, Token Terminal, DefiLlama, growthepie, L2BEAT, block explorers, etc.), give a data-driven answer to this question.

Some considerations:

1. **Diagnose the revenue.** Decompose the revenue being made through OP Mainnet over the last 12 months including any patterns in what has changed and why. Our share means sequencer revenue: the fees users pay on OP Mainnet, minus what OP pays to post data to Ethereum. Compare it with what apps earn.
2. **Identify the customers.** Treat the apps and contracts generating revenue as customers of OP Mainnet. Are there any other customer targets we should be considering?
3. **Write the recommendation.** Include in your presentation the finding, the evidence, the business implication, and the recommended action. Include any relevant metrics you would track to measure success.

What we're evaluating

- **Framing:** did you answer the question leadership asked, or a more convenient one?
- **Metric judgment:** did you choose measures that connect to revenue and business economics, and did you explain why?
- **Commercial reasoning:** does the business case have real assumptions and sensitivities?
- **Communication:** can a Finance or BD lead understand your recommendation and act?
- **Process:** did you work in a way where errors can be recovered from quickly? (good programming practices, good documentation, etc.)

Internal data we provide (CSVs):

#	Dataset	Grain	What it is for
1	OP Mainnet fees: execution, L1 data, total. ETH + USD	daily	This is the revenue OP earns. You need it to answer the first question.
2	ETH price	daily	Fees are in ETH. Use this to convert to USD and to separate price effects from usage.
3	Txs, failed txs, active senders	daily	Basic demand. Use it to split revenue into volume and price per tx.
4	New addresses (first tx ever)	daily	Growth signal. It is raw input and points to no conclusion.
5	Contract deployments	daily	Builder activity. It gives a supply-side view of customers.
6	Fees + txs + senders by contract, every contract above a minimum number of txs in any month	daily	The core customer table. The cutoff is neutral, so ranking, concentration, and churn choices are yours.
7	Labels: contract → project, category	static	Raw addresses are unreadable. Use the labels to group contracts into apps as you choose.
8	App fees + app revenue by protocol	daily	This answers "who is making money." It shows what apps earn next to what they pay OP.
